INTRODUCTION TO ALL THE ISSUES

This paper presents calculations of various economic indicators for the Russian Federation in April to September of 2019, which were performed using time series models developed as a result of research conducted by the Gaidar Institute over the past few years¹. A method of forecasting falls within the group of formal or statistical methods. In other words, the calculated values neither express the opinion nor expert evaluation of the researcher, rather they are calculations of future values for a specific economic indicator, which were performed using formal ARIMA-models (p, d, q) given a prevailing trend and its, in some cases, significant changes. The presented forecasts are of inertial nature, because respective models rely upon the dynamics of the data registered prior to the moment of forecasting and depend too heavily on the trends, which are typical of the time series in the period immediately preceding the time horizon to be forecast. The foregoing calculations of future values of economic indicators for the Russian Federation can be used in making decisions on economic policy, provided that the general trends, which were seen prior to forecasting for each specific indicator, remain the same, i.e. prevailing long-term trends will see no serious shocks or changes in the future.

Despite that there is a great deal of data available on the period preceding the crisis of 1998, models of forecasting were analyzed and constructed using only the time horizon which followed August 1998. This can be explained by the findings of previous studies², which concluded, among other key inferences, that the quality of forecasts was deteriorated in most of the cases when the data on the pre-crisis period was used. Additionally, it currently seems incorrect to use even shorter series (following the crisis of 2008), because statistical characteristics of models based on such a short time horizon are very poor.

Models for the economic indicators in question were evaluated using standard methods of time series analysis. Initially, the correlograms of the studied series and their first differences were analyzed in order to determine the maximum number of delayed values to be included into the specifications of a model. Then, the results of analyzed correlograms served as the basis for testing all the series for weak stationarity (or stationarity around the trend) using the Dickey–Fuller test. In some cases, the series were tested for stationarity around the segmented trend using Perron and Zivot–Andrews tests for endogenous structural changes³.

The series were broken down into weak stationary, stationary near the trend, stationary near the trend with structural change or difference stationary, and then models, which corresponded to each type (regarding the levels and including, if necessary, the trend or segmented trend or differences), were evaluated. The Akaike and Schwartz information criteria, the properties of models' residuals (lack of autocorrelation, homoscedasticity and normality) and the quality of the in-sample-forecasts based on these models were used to choose the best model. Forecast values were calculated for the best of the models constructed for each economic indicator.

Additionally, the Bulletin presents future monthly values of the CPI, which were calculated using models developed at the Gaidar Institute, and volumes of imports/exports from/to all countries, which were calculated using structural models (SM). The forecast values based on the structural models may, in some cases, produce better results than ARIMA-models do, because structural models are constructed by adding information of the dynamics of exogenous variables. Besides, the use of structural forecasts in making aggregated forecasts (i.e. forecasts obtained as average value from several models) may help make forecast values more accurate.

See, for example, R.M. Entov, S.M. Drobyshevsky, V.P. Nosko, A.D. Yudin. The Econometric Analysis of the Time Series of the Main Macroeconomic Indices. Moscow, IET, 2001; R.M. Entov, V.P. Nosko, A.D. Yudin, P.A. Kadochnikov, S.S. Ponomarenko. Problems of Forecasting of Some Macroeconomic Indices. Moscow, IET, 2002; V. Nosko, A. Buzaev, P. Kadochnikov, S. Ponomarenko. Analysis of the Forecasting Parameters of Structural Models and Models with the Outputs of the Polls of Industries. Moscow, IET, 2003; M.Yu. Turuntseva and T.R. Kiblitskaya, Qualitative Properties of Different Approaches to Forecasting of Social and Economic Indices of the Russian Federation. Moscow, IET, 2010.

lbid.

See.: Perron, P. Further Evidence on Breaking Trend Functions in Macroeconomic Variables, *Journal of Econometrics*, 1997, 80, pp. 355–385; Zivot, E. and D.W.K. Andrews. Further Evidence on the Great Crash, the Oil-Price Shock, and Unit-Root Hypothesis. *Journal of Business and Economic Statistics*, 1992, 10, pp. 251–270.

The dynamics of the Consumer Price Index was modeled using theoretical assumptions arising from the monetary theory. The following was used as explanatory variables: money supply, output volume, the dynamics of the ruble-dollar exchange rate, which reflects the dynamics of alternative cost of money-keeping. The model for the Consumer Price Index also included the price index in the electric power industry, because the dynamics of manufacturers' costs relies heavily on this indicator.

The baseline indicator to be noted is the real exchange rate, which can influence the value of exports and imports, and its fluctuations can result in changes to the relative value of domestically-produced and imported goods, though the influence of this indicator turns out to be insignificant in econometric models. Global prices of exported resources, particularly crude oil prices, are most significant factors, which determine the dynamics of exports: a higher price leads to greater exports of goods. The level of personal income in the economy (labor costs) was used to describe the relative competitive power of Russian goods. Fictitious variables D12 and D01 – equal to one in December and January and zero in other periods – were added so that seasonal fluctuations were factored in. The dynamics of imports is effected by personal and corporate incomes whose increase triggers higher demand for all goods including imported ones. The real disposable cash income reflects the personal income; the Industrial Production Index reflects the corporate income.

The forecast values of foreign exchange rates were also calculated using structural models of their dependence on global crude oil prices.

The forecast values of explanatory variables, which are required for forecasting on the basis of structural models, were calculated using ARIMA-models (p, d, q).

The paper also presents calculations of the values of the Industrial Production Index, the Producer Price Index and the Total Unemployment Index, which were calculated using the results of business surveys conducted by the Gaidar Institute. Empirical studies show¹ that the use of series of business surveys as explanatory variables ² in forecasting models can make forecasting more accurate on the average. Future values of these indicators were calculated using ADL-models (seasonal autoregressive delays were added).

The Consumer Price Index and the Producer Price Index are also forecast using large datasets (factor models – FM). The construction of factor models relies basically on the evaluation of the principal components of a large dataset of socio-economic indicators (112 indicators in this case). The lags of these principal components and the lags of the explanatory variable are used as explanatory variables in these models. A quality analysis of the forecasts obtained for different configurations of the factor models was used to choose a model for the CPI, which included 9th, 12th and 13th lags of the four principal components, as well as 1st and 12th lags of the variable itself, and a model for the PPI, which included 8th, 9th and 12th lags of the variable itself.

All calculations were performed using the Eviews econometric package.

See, for example: V. Nosko, A. Buzaev, P. Kadochnikov, S. Ponomarenko. *The Analysis of Forecasting Parameters of Structural Models and Models with Business Surveys' Findings*. Moscow, IEP, 2003.

Used as explanatory variables were the following series of the business surveys: the current/expected change in production, the expected changes in the solvent demand, the current/expected price changes and the expected change in employment.

cesses around the trend with an endogenous structural change; the series of the Rosstat and the NRU HSE chain IIPs for manufacturing, for primary metals and fabricated metal products, as well as the NRU HSE chain IIP for mining and Rosstat chain IIP for machinery and equipment are identified as stationary processes around the trend with two endogenous structural *Note:* In the time spans under review, the series of the Kosstat and the NKU HSE chain indices of IIP, as well as the NKU HSE chain IIP for manufacturing are identified as stationary prochanges. The time series of other chain indices are stationary at levels.

1 It is to be noted that for making of forecasts so-called "raw" indices (without seasonal and calendar adjustment) were used and for that reason in most models existence of the season factor is taken into account and, as a consequence, the obtained outputs reflect the seasonal dynamics of the series.

INDUSTRIAL PRODUCTION AND RETAIL SALES

Industrial production

For making forecast for April to September 2019, the series of monthly data of the indices of industrial production released by the Federal State Statistics Service (Rosstat) from January 2002 January 2019, as well as the series of the base indices of industrial production released by the National Research University Higher School of Economics (NRU HSE¹) over the period from January 2010 to February 2019 were used (the corrected value of January 2010 was equal to 100%). The forecast values of the series were calculated on the basis of ARIMA-class models. The forecast values of the Rosstat and the NRU HSE indices of industrial production are calculated using business surveys (BS) as well. The obtained results are shown in Table 1.

As seen from *Table 1*, the Rosstat average² growth of the industrial production index posted 2.3% for April-September 2019 against the same period of the previous year for the industry as a whole. As for the NRU HSE industrial production index, the indicator constitutes 2.5%.

In April-September 2019, the average monthly gain of the Rosstat and the NRU HSE industrial production indexes for mining and quarrying amount to 2.6% and 2.7%, respectively.

The average gain of the industrial production index in manufacturing industry according to Rosstat for April-September 2019 amounts to 1.3% compared to the same period of the previous year and the NRU HSE industrial production index in manufacturing industry comes to 1.6%. The monthly production of food products is forecast to grow on average by 3.2% and 0.7% for the Rosstat and NRU HSE indexes, respectively. The production of coke and petroleum products is forecast to grow on average by 0.1% and 0.1% for the Rosstat and NRU HSE indexes, respectively. The average monthly change in the industrial production index for primary metals and fabricated metal products for April-September 2019 computed by Rosstat and the NRU HSE constitute 2.7% and 1.0%, respectively. Manufacturing of machinery and equipment is forecast to increase on average by (-0.9%) and (-1.7%) for the Rosstat and the NRU HSE indexes, respectively.

The average gain of the industrial production index for electricity, gas, and steam supply; for air conditioning computed by Rosstat for April-September 2019 in comparison with the same period of the previous year constitutes 0.8%; the same indicator for the NRU HSE industrial production index comes to 1.0% per month.

Retail Sales

This section (Table 2) presents forecasts of monthly retail sales made on the basis of monthly Rosstat data over January 1999 – March 2019.

As seen from *Table 2*, the average forecast increment of the monthly trade turnover for April to September 2019 against the corresponding period of 2018 will amount to around 4.8%.

The average monthly real trade turnover is forecast to grow at around 0.8%.

Table 2
Calculations of forecast values of the retail sales and the real retail sales

F	orecast value according to	ARIMA-model

Note: over the period from January 1999 to January 2019, the series of the chain producer price index for machinery are identified as a stationary process around the trend with two endogenous structural changes. The series of other chain price indices are stationary at levels.

FOREIGN TRADE INDICES

Model calculations of forecast values of the export and export to countries outside the CIS and the import and import from countries outside the CIS were made on the basis of the models of time series and structural models evaluated on the basis of the monthly data over the period from September 1998 to February 2019 on the basis of the data released by the Central Bank of Russia.¹ The results of calculations are shown in Table 3.

Export, import, export outside the CIS and import from the countries outside the CIS are forecast to grow on average at 12.3%, 8.4%, 12.7%, and 10.7%, respectively for April-September 2019 against the same period of 2018. The average forecast surplus volume of the trade balance with all countries for April-September 2019 will amount to \$109.6bn, which reflects an increase of 17.7% on the same period of 2018.

DYNAMICS OF PRICES

The Consumer Price Index and Producer Price Index

This section presents calculations of forecast values of the consumer price index and producer price index (as regards both the industry in general and some types of its activities under the National Industry Classification Standard (NICS)) made on the basis of the time-series models evaluated on the basis of the data released by Rosstat over the period from January 1999 to January 2019². Table 4 presents the results of model calculations of forecast values over April and September 2019 in accordance with ARIMA models, structural models (SM) and models computed with the help of business surveys (BS).

The consumer price index is forecast to grow at an average monthly rate of 0.4% for April-September 2019. The industrial producer price increment for the period under review is forecast to average 0.8% per month.

The producer price indexes are forecast to grow at average monthly rate for April-September 2019: for mining and quarrying 0.5%, manufacturing 0.8%, utilities (electricity, gas, and steam) 0.5%, food products 0.7%, textile and sewing industry 0.6%, wood products 0.5%, pulp and paper industry 0.8%, coke and refined petroleum 2.0%, for chemical industry 1.1%, for basic metals and fabricated metal 0.2%, for machinery and equipment 0.3%, and for motor vehicles manufacture 0.4%.

The Cost of the Monthly per Capita Minimum Food Basket

This section presents calculations of forecast values of the cost of the monthly per capita minimum food basket over April and September of 2019. The forecasts were made on the basis of time series with use the Rosstat data over the period from January 2000 to March 2019. The results are shown in Table 5.

Table 5
The forecast of the cost of the monthly per capita minimum food basket

May 19	4.4			
Jun 19	2.3			
Jul 19	3.1			
Aug 19	5.7			
Sep 19	8.7			

Note: the series of the cost of the monthly per capita minimum food basket over the period from January 2000 March 2019 are stationary in the first-order differences.

¹ The data on the foreign trade turnover is calculated by the CBR in accordance with the methods for making of the balance of payment in prices of the exporter-country (FOB) in billion USD.

² Structural models were evaluated in the period from October 1998.

As can be seen from *Table 5*, the minimum set of food products' cost is forecast to grow compared to the corresponding period of the previous year. At the same time, the minimum set of food products is forecast to average RUB 4,158.3. The minimum set of food products cost is forecast to grow on average at around 4.9% against the same period of the previous year.

Indices of Freight Rates

This section presents calculations of forecast values of freight rate indices on cargo carriage¹, made on the basis of time-series models evaluated on the Rosstat data over the period from September 1998 to February 2019. Table 6 shows the results of model calculations of forecast values in April-September of 2019. It should be noted that some of the indices under review (for instance, the pipeline rate index) are adjustable ones and for that reason their behavior is hard to describe by means of the time-series models. As a result, the future values may differ greatly from the real ones in case of the centralized increase of rates in the period of forecasting or in case of absence of such an increase in the forecasting period, but with it taking place shortly before the beginning of that period.

According to the forecast results for April-September 2019, the composite index of transport tariffs will be growing at an average monthly rate of 1.4%. In April 2019, the seasonal increment of this index is projected at 4.0 p.p. and in July 2019 – 3.6 p.p. The index of motor freight tariffs will not be changing during these six months. The index of pipeline tariffs will also be growing at an average monthly rate of 1.2%. In April 2019, the seasonal growth of the index is expected at 6.7 p.p.

World Prices of Natural Resources

This section presents calculations of such average monthly values of Brent crude prices (US\$ per barrel), the aluminum prices (US\$ per ton), the gold prices (\$ per ounce), the copper prices (US\$ per ton), and the nickel prices (US\$ per ton) over April to September of 2019 as were received on the basis of nonlinear models of time series evaluated on the basis of the IMF data over the period from January 1980 to February 2019.

Table 6

Aug 18	100.2	100.1	100.3
Sep 18	100.1	100.0	99.9

Note: over the period from September 1998 to February 2019, the series of the freight rates index were identified as stationary ones; the other series were identified as stationary ones over the period from November 1998 February 2019, too; fictitious variables for taking into account particularly dramatic fluctuations were used in respect of all the series.

The crude oil price is forecast to average around \$66.3 per barrel, which is below its corresponding year-earlier indexes on average by 14.6%. The aluminum prices are forecast to average around \$1,936 per ton and their average forecast slide constitutes around 10% compared to the same level of last year. The gold price is forecast to average \$1,369 per ounce. The copper price is forecast to average \$6,835 per ton, and prices for nickel – around \$13,620 per ton. The average forecast price increase for gold constitutes

The paper presents a review of the composite freight rate index on freight transport and the motor load freight rate index, as well as the pipeline rate index. The composite freight rate index is computed on the basis of the freight rate indices by individual types of transport: rail, pipeline, shipping, domestic water-borne, and motor load freight and air service (for more detailed information, pls. refer, for instance, to: *Prices in Russia*. The Official Publication of Goskomstat of RF, 1998).

around 9.0 %, the average gain of copper prices – around 9%, and average slide off nickel prices – 1% against the corresponding level of last year.

Note: over the period from January 1980 to February 2019, the series of prices of crude oil, nickel, gold, copper, and aluminum are series of DS type.

MONETARY INDICES

The future values of the monetary base (in the narrow definition: cash funds and the Fund of Mandatory Reserves (FMR) and M₂ monetary aggregate over the period from April to September of 2019 were received on the basis of models of time-series of respective indices calculated by the CBR¹ over the period from October 1998 to March 2019. Table 8 presents the results of calculations of forecast values and actual values of those indices in the same period of previous year. It is to be noted that due to the fact that the monetary base is an instrument of the CBR policy, forecasts of the monetary base on the basis of time-series models are to a certain extent notional as the future value of that index is determined to a great extent by decisions of the CBR, rather than the inherent specifics of the series.

In April-September 2019, the monetary base will be growing at an average monthly rate of 0.7%. The monetary index M_2 will not be changing on average.

Mata	01/04 tho	pariod from Oc	tabar 10	00 to March of

Note: over the period from October 1998 to March of 2019, all the time series of monetary indices were attributed to the class of series which are stationary in the first-order differences and have an explicit seasonal component.

The data on the specific month is given in accordance with the methods of the CBR as of the beginning of the following month.

INTERNATIONAL RESERVES

This section presents the outputs of the statistical estimation of such future values of the international reserves of the Russian Federation¹ as were received on the basis of evaluation of the model of time series of the gold and foreign exchange reserves on the basis of the data released by the CBR over the period from October 1998 to February of 2019. That index is forecast without taking into account a decrease in the amount of reserves due to foreign debt payment and for that reason the values of the volumes of the international reserves in the months where foreign debt payments are made may happen to be overestimated (or otherwise underestimated) as compared to the actual ones.

Subsequent to the forecast results for April-September 2019, the international reserves will be growing at an average monthly rate of 0.6%.

FOREIGN EXCHANGE RATES

The model calculations of prospective values of the foreign exchange rates (RUB per USD and USD per euro) were made on the basis of assessment of the time series models (ARIMA) and structural models (SM) of the relevant indicators released by the Central Bank of Russia as of the last date of each month over the periods from October 1998 to March 2019 and from February 1999 to March 2019², respectively.

In April-September 2019, USD/RUB average exchange rate is forecast in the amount of RUB 65.58 for USD by two models. Over the period under review, Euro/USD exchange rate is forecast during the forecast period at USD 1.13 per 1 euro.

THE LIVING STANDARD INDEXES

This section (Table 11) presents calculations of forecast values of indices of real wages, real disposable income and real income ³ as were received on the basis of the model of time series of respective indices computed by Rosstat

Table 9

Aug 18	68.	.08	1.:	16
Sep 18	65.	.59	1.:	16

Note: over the respective periods, the series under review were identified as integrated series of the first order with a seasonal component.

¹ The data on the volume of the gold and foreign exchange reserves is presented as of the first day of the following month.

² The authors use the IMF data regarding Euro/USD over the period from January 1999 to February 2019 and regarding USD/RUR over the period from October 1998 to March 2019. Data regarding Euro/USD for March 2019 were taken from the exchange rate statistics site WWW.oanda.com.

Real cash income is a relative index which is calculated by means of division of the index of the nominal size (which was actually formed in the period under review) of households' cash income by the CPI. Real disposable cash income is cash income minus mandatory payments and contributions. (See: Rossiisky Statistichesky Ezhegodnik, Moscow, Rosstat, 2004, p. 212).

and taken over the period from January 1999 to January 2019. The above indices depend to a certain extent on the centralized decisions on raising of wages and salaries to public sector workers, as well as those on raising of pensions, scholarships and allowances; such a situation introduces some changes in the dynamics of the indices under review. As a result, the future values of the indices of real wages and real disposable income calculated on the basis of the series which last observations are either considerably higher or lower than the previous ones due to such a raising may differ greatly from those which are implemented in reality.

According to the results presented in *Table 11*, the real disposable cash income will not change on average compared to the previous year. The forecast average monthly gain of the real cash income will amount to 0.1%; the accrued wages will amount to 3.0%.

Table 11
The forecast of the living standard indexes

	Real disposable cash income	Real cash income	Real accrued wages
Fo	orecast values accordi (% of the respective	ng to ARIMA-ı	models
Apr 19	98.5	99.2	101.5

May 18	99.4	100.7	107.6
Jun 18	99.8	100.6	107.2
Jul 18	101.5	102.1	107.5
Aug 18	97.7	98.9	106.8
Sep 18	95.9	97.5	104.9

Note: for calculating purposes the series of the real disposable cash income, real cash income and real accrued wages in the base form were used (January 1999 was adopted as a base period). Over the period from January 1999 to January 2019, those series were attributed to the class of processes, which are stationary in differences and have an explicit seasonal component.

EMPLOYMENT AND UNEMPLOYMENT

For the purpose of calculation of the future values of the employment (of the number the gainfully employed population) and the unemployment (the total number of the unemployed), models of the time series evaluated over the period from October 1998 to January 2019 on the basis of the monthly data released by Rosstat¹ were used. The unemployment was calculated on the basis of the models with results of the findings from business surveys² too.

It is to be noted that feasible logical inconsistencies³ in forecasts of employment and unemployment which totals should be equal to the index of economically active population may arise due to the fact that each series is forecast individually and not as a difference between the forecast values of the economically active population and another index.

According to ARIMA-model forecast (*Table 12*), in April-September 2019, the increase of the number of employed in the economy will average 0.0% per month against the corresponding period of the previous year.

The average decrease of the total number of jobless is forecast to average 0.9% per month against the same period of last year. To note, the models demonstrate significantly different dynamics of unemployment over the period under review.

¹ The index is computed in accordance with the methods of the International Labor Organization (ILO) and is given as of the month-end.

The model is evaluated over the period from January 1999 to January 2019.

For example, deemed as such a difference may be a simultaneous decrease both in the employment and the unemployment. However, it is to be noted that in principle such a situation is possible provided that there is a simultaneous decrease in the number of the economically active population.

Table 12
Calculation of forecast values of the indices the employment and the unemployment

	Emplo	yment (ARIMA)		Unemployment (/	ARIMA)	Unemployment (BS)						
	Million people	Growth on the respective month of previ- ous year (%)	Million people	Growth on the respective month of previous year (%)	% of the index of the number of the gainfully employed population	Million people	Growth on the respective month of previous year (%)	% of the index of the number of the gainfully employed population				
Apr 19	71.8	-0.6	3.6	-4.0	4.9	3.7	0.0	5.2				
May 19	72.3	-0.3	3.4	-5.5	4.7	3.6	0.4	5.0				
Jun 19	72.6	0.1	3.3	-4.4	4.6	3.6	2.9	5.0				
Jul 19	73.0	0.4	3.4	-5.7	4.6	3.7	2.5	5.1				
Aug 19	73.5	0.1	3.3	-5.1	4.5	3.6	4.2	4.9				
Sep 19	73.1	0.0	3.3	-2.9	4.5	3.6	7.1	4.9				
		For refe	rence: act	tual values in the sa	ame periods of 20	18 (millio	on people)					
Apr 18	8 72.3 3.7											
May 18		72.5			3.6							
Jun 18		72.5	3.5									
Jul 18		72.7	3.6									
Aug 18		73.4		3.5								
Sep 18	73.1 3.4											

Note: over the period from October 1998 to January 2019, the series of employment is a stochastic process which is stationary around the trend. The series of unemployment is a stochastic process with the first order integration. Both indices include seasonal component.
