

INTRODUCTION TO ALL THE ISSUES

This paper presents calculations of various economic indicators for the Russian Federation in February-July of 2018, which were performed using time series models developed as a result of research conducted by the Gaidar Institute over the past few years¹. A method of forecasting falls within the group of formal or statistical methods. In other words, the calculated values neither express the opinion nor expert evaluation of the researcher, rather they are calculations of future values for a specific economic indicator, which were performed using formal ARIMA-models (p, d, q) given a prevailing trend and its, in some cases, significant changes. The presented forecasts are of inertial nature, because respective models rely upon the dynamics of the data registered prior to the moment of forecasting and depend too heavily on the trends, which are typical of the time series in the period immediately preceding the time horizon to be forecast. The foregoing calculations of future values of economic indicators for the Russian Federation can be used in making decisions on economic policy, provided that the general trends, which were seen prior to forecasting for each specific indicator, remain the same, i.e. prevailing long-term trends will see no serious shocks or changes in the future.

Despite that there is a great deal of data available on the period preceding the crisis of 1998, models of forecasting were analyzed and constructed using only the time horizon which followed August 1998. This can be explained by the findings of previous studies², which concluded, among other key inferences, that the quality of forecasts was deteriorated in most of the cases when the data on the pre-crisis period was used. Additionally, it currently seems incorrect to use even shorter series (following the crisis of 2008), because statistical characteristics of models based on such a short time horizon are very poor.

Models for the economic indicators in question were evaluated using standard methods of time series analysis. Initially, the correlograms of the studied series and their first differences were analyzed in order to determine the maximum number of delayed values to be included into the specifications of a model. Then, the results of analyzed correlograms served as the basis for testing all the series for weak stationarity (or stationarity around the trend) using the Dickey–Fuller test. In some cases, the series were tested for stationarity around the segmented trend using Perron and Zivot–Andrews tests for endogenous structural changes.³

The series were broken down into weak stationary, stationary near the trend, stationary near the trend with structural change or difference stationary, and then models, which corresponded to each type (regarding the levels and including, if necessary, the trend or segmented trend or differences), were evaluated. The Akaike and Schwartz information criteria, the properties of models' residuals (lack of autocorrelation, homoscedasticity and normality) and the quality of the in-sample-forecasts based on these models were used to choose the best model. Forecast values were calculated for the best of the models constructed for each economic indicator.

Additionally, the Bulletin presents future monthly values of the CPI, which were calculated using models developed at the Gaidar Institute, and volumes of imports/exports from/to all countries, which were calculated using structural models (SM). The forecast values based on the structural models may, in some cases, produce better results than ARIMA-models do, because structural models are constructed by adding information of the dynamics of exogenous variables. Besides,

INTRODUCTION TO ALL THE ISSUES

the use of structural forecasts in making aggregated forecasts (i.e. forecasts obtained as average value from several models) may help make forecast values more accurate.

The dynamics of the Consumer Price Index was modeled using theoretical assumptions arising from the monetary theory. The following was used as explanatory variables: money supply, output volume, the dynamics of the ruble-dollar exchange rate, which reflects the dynamics of alternative cost of money-keeping. The model for the Consumer Price Index also included the price index in the electric power industry, because the dynamics of manufacturers' costs relies heavily on this indicator.

The baseline indicator to be noted is the real exchange rate, which can influence the value of exports and imports, and its fluctuations can result in changes to the relative value of domestically-produced and imported goods, though the influence of this indicator turns out to be insignificant in econometric models. Global prices of exported resources, particularly crude oil prices, are most significant factors, which determine the dynamics of exports: a higher price leads to greater exports of goods. The level of personal income in the economy (labor costs) was used to describe the relative competitive power of Russian goods. Fictitious variables D12 and D01 – equal to one in December and January and zero in other periods – were added so that seasonal fluctuations were factored in. The dynamics of imports is effected by personal and corporate incomes whose increase triggers higher demand for all goods including imported ones. The real disposable cash income reflects the personal income; the Industrial Production Index reflects the corporate income.

The forecast values of foreign exchange rates were also calculated using structural models of their dependence on global crude oil prices.

The forecast values of explanatory variables, which are required for forecasting on the basis of structural models, were calculated using ARIMA-models (p, d, q).

The paper also presents calculations of the values of the Industrial Production Index, the Producer Price Index and the Total Unemployment Index, which were calculated using the results of business surveys conducted by the Gaidar Institute. Empirical studies show¹ that the use of series of business surveys as explanatory variables ² in forecasting models can make forecasting more accurate on the average. Future values of these indicators were calculated using ADL-models (seasonal autoregressive delays were added).

The Consumer Price Index and the Producer Price Index are also forecast using large datasets (factor models – FM). The construction of factor models relies basically on the evaluation of the principal components of a large dataset of socio-economic indicators (112 indicators in this case). The lags of these principal components and the lags of the explanatory variable are used as explanatory variables in these models. A quality analysis of the forecasts obtained for different configurations of the factor models was used to chose a model for the CPI, which included 9th, 12th and 13th lags of the four principal components, as well as 1st and 12th lags of the variable itself, and a model for the PPI, which included 8th, 9th and 12th lags of the four principal components, as well as 1st, 3rd and 12th lags of the variable itself.

All calculations were performed using the Eviews econometric package.

¹ See, for example: V. Nosko, A. Buzaev, P. Kadochnikov, S. Ponomarenko. The Analysis of Forecasting Parameters of Structural Models and Models with Business Surveys' Findings. Moscow, IEP, 2003.

² Used as explanatory variables were the following series of the business surveys: the current/expected change in production, the expected changes in the solvent demand, the current/expected price changes and the expected change in employment.

Note: in the time spans under review, the series of the Rosstat and the NRU HSE chain indices of IIP, as well as the NRU HSE chain IIP for manufacturing are identified as fabricated metal products, as well as the NRU HSE chain IIP for mining and Rosstat chain IIP for machinery and equipment are identified as stationary processes around the stationary processes around the trend with an endogenous structural change; the series of the Rosstat and the NRU HSE chain IIPs for manufacturing, for primary metals and

trend with two endogenous structural changes. The time series of other chain indices are stationary at levels.

1 It is to be noted that for making of forecasts so-called "raw" indices (without seasonal and calendar adjustment) were used and for that reason in most models existence of the season factor is taken into account and, as a consequence, the obtained outputs reflect the seasonal dynamics of the series.

INDUSTRIAL PRODUCTION AND RETAIL SALES

Industrial production

For making forecast for February–July 2018, the series of monthly data of the indices of industrial production released by the Federal State Statistics Service (Rosstat) from January 2002 – November 2017, as well as the series of the base indices of industrial production released by the National Research University Higher School of Economics (NRU HSE¹) over the period from January 2010 to December 2017 were used (the corrected value of January 2010 was equal to 100%). The forecast values of the series were calculated on the basis of ARIMA-class models. The forecast values of the Rosstat and the NRU HSE indices of industrial production are calculated using business surveys (BS) as well. The obtained results are shown in Table 1.

As seen from *Table 1*, the Rosstat industrial production index posted growth of 0.3% in February–July 2018 compared to the same period of the previous year for industry as a whole. As for the NRU HSE industrial production index, this indicator constitutes 0.4%. To note, forecasts of both indexes along different models (ARIMA and BS) demonstrate differently directed dynamic.

The average monthly contraction of the Rosstat industrial production index and for the NRU HSE industrial production index for mining for February–July 2018 comes to 1.7 % and 2.2%, respectively.

In February–July 2018 in comparison with the same period of last year, the average growth of the Rosstat industrial production index for manufacturing comes to 1.0% and the NRU HSE industrial production index to 0.5%. The average monthly values of the Rosstat industrial production index and the NRU HSE industrial production index for food products constitute 3.1% and 5.4%, respectively. The production of coke and petroleum products is forecast to average 2.5% and 2.5% for the Rosstat and NRU HSE indexes, respectively. The average monthly values of the industrial production index for primary metals and fabricated metal products for February–July 2018 computed by Rosstat and the NRU HSE constitute 28.7% and 0.2%), respectively. Manufacturing of machinery and equipment is forecast on average at 0.8% and 0.0% for the Rosstat and the NRU HSE indexes, respectively.

The average growth of the industrial production index for electricity, gas, and water supply; for air conditioning computed by Rosstat for February–July 2018 in comparison with the same period of the previous year constitutes 0.3%; the same indicator for the NRU HSE industrial production index comes to 0.7%.

Retail Sales

This section (Table 2) presents forecasts of monthly retail sales made on the basis of monthly Rosstat data over January 1999 – December 2017.

As seen from *Table 2*, the monthly trade turnover is forecast to grow on average at around 3.6% in February–July 2018 against the corresponding period of 2017.

The monthly real trade turnover is forecast to grow at around 0.9% in February–July 2018 compared to the corresponding period of 2017.

Note: over the period from January 1999 to November 2017, the series of the chain producer price index for machinery are identified as a stationary process around the trend with two endogenous structural changes. The series of other chain price indices are stationary at levels.

FOREIGN TRADE INDICES

Model calculations of forecast values of the export and export to countries outside the CIS and the import and import from countries outside the CIS were made on the basis of the models of time series and structural models evaluated on the basis of the monthly data over the period from September 1998 to December 2017 on the basis of the data released by the Central Bank of Russia¹. The results of calculations are shown in Table 3.

Export, import, export outside the CIS and import from the countries outside the CIS are forecast to grow at 21.1%, 23.8%, 19.1%, and 21.5%, respectively in February–July 2018 against the same period of 2017. The average forecast surplus volume of the trade balance with all countries for February–July 2018 will amount to \$59.5bn which reflects increase of 15.0% on the same period of 2017.

DYNAMICS OF PRICES

The Consumer Price Index and Producer Price Index

This section presents calculations of forecast values of the consumer price index and producer price index (as regards both the industry in general and some types of its activities under the National Industry Classification Standard (NICS)) made on the basis of the time-series models evaluated on the basis of the data released by Rosstat over the period from January 1999 to Novem-

ber 2017². Table 4 presents the results of model calculations of forecast values over February–July of 2018 in accordance with ARIMA models, structural models (SM) and models computed with the help of business surveys (BS).

The consumer price index is forecast to grow at an average monthly rate of 0.4% in February–July 2018. The producer price index (PPI) for the same period is also forecast to average 0.5% per month.

The producer price indexes computed by Rosstat are forecast to grow at average monthly rates in February–July 2018: for mining and quarrying 1.2%, manufacturing 0.6 percent, utilities (electricity, gas, and water) 0.3%, food products 0.3%, textile and sewing industry 0.8%, wood products 0.4%, pulp and paper industry 0.4%, coke and refined petroleum 2.2%, for chemical industry 0.8%, for basic metals and fabricated metal 1.0%, for machinery and equipment 0.3%, and for motor vehicles manufacture 0.5%.

The Cost of the Monthly per Capita Minimum Food Basket

This section presents calculations of forecast values of the cost of the monthly per capita minimum food basket over February and July 2018.

Table 5
THE FORECAST OF THE COST OF THE MONTHLY
PER CAPITA MINIMUM FOOD BASKET

Apr 17	3872.5		
May 17	4036.7		
Jun 17 4233.2			
Jul 17	4066.8		
	spected growth		
on the respective	month of the previous year (%)		
Feb 18	6.0		
Mar 18	6.6		
Apr 18	5.6		
May 18	3.6		
Jun 18	0.3		
Jul 18	0.6		

Note: the series of the cost of the monthly per capita minimum food basket over the period from January 2000 to November 2017 are stationary in the first-order differences.

¹ The data on the foreign trade turnover is calculated by the CBR in accordance with the methods for making of the balance of payment in prices of the exporter-country (FOB) in billion USD.

² Structural models were evaluated in the period from October 1998.

DYNAMICS OF PRICES

The forecasts were made on the basis of time series with use the Rosstat data over the period from January 2000 to November 2017. The results are shown in Table 5.

As can be seen from *Table 5*, the minimum set of food products' cost is forecast to grow compared to the corresponding period of the previous year. At the same time, the minimum set of food products is forecast to average RUB 4,100.0. The minimum set of food products cost is forecast to grow on average around 3.8% compared to the level of the corresponding period of the previous year.

Indices of Freight Rates

This section presents calculations of forecast values of freight rate indices on cargo carriage¹, made on the basis of time-series models evaluated on the Rosstat data over the period from September 1998 to November 2017. Table 6 shows the results of model calculations of forecast values in February-July 2018. It should be noted that some of the indices under review (for instance, the pipeline rate index) are adjustable ones and for that reason their behavior is hard to describe by means of the time-series models. As a result, the future values may differ greatly from the real ones in case of the centralized increase of rates in the period of forecasting or in case of absence of such an increase in the forecasting period, but with it taking place shortly before the beginning of that period.

According to the forecast results for February–July 2018, the composite index of transport tariffs will increase on average 1.6% per month. In April and July 2018, the seasonal growth of the index is expected by 3.8 and 3.6 p.p., respectively.

The index of motor freight tariffs will grow in the course of given six months at an average rate of 0.1%.

The index of pipeline tariffs will be increasing in the course of the next six months at a monthly average rate of 1.2%. In April 2018, the seasonal increase of the index is expected by 7.0 p.p.

Table 6

May 17	100.0	100.1	100.1
Jun 17	100.2	100.0	100.2
Jul 17	106.8	100.1	114.0

Note: over the period from September 1998 to November 2017, the series of the freight rates index were identified as stationary ones; the other series were identified as stationary ones over the period from September 1998 to November 2017, too; fictitious variables for taking into account particularly dramatic fluctuations were used in respect of all the series.

World Prices of Natural Resources

This section presents calculations of such average monthly values of Brent crude prices (US\$ per barrel), the aluminum prices (US\$ per ton), the gold prices (\$ per ounce), the copper prices (US\$ per ton), and the nickel prices (US\$ per ton) over February–July 2018 as were received on the basis of nonlinear models of time series evaluated on the basis of the IMF data over the period from January 1980 to December 2017.

¹ The paper presents a review of the composite freight rate index on freight transport and the motor load freight rate index, as well as the pipeline rate index. The composite freight rate index is computed on the basis of the freight rate indices by individual types of transport: rail, pipeline, shipping, domestic water-borne, and motor load freight and air service (for more detailed information, pls. refer, for instance, to: *Prices in Russia*. The Official Publication of Goskomstat of RF, 1998).

The crude oil price is forecast to average around \$65.5 per barrel, which is above its corresponding year-earlier indexes on average by 26.6%. The Aluminum price is forecast to average around \$2,390.0 per ton and their average forecast increment constitutes around 26.0% compared to the same level of last year. The gold price is forecast to average \$1,276.0 per ounce. The copper price is forecast to average \$7,726 per ton, and prices for nickel – around \$14,156 per ton. The average forecast price increase for gold constitutes around 2.0%, average increase of copper prices – around 32.0%, and average increase of nickel prices – 45.0% compared to the corresponding level of last year.

MONETARY INDICES

The future values of the monetary base (in the narrow definition: cash funds and the Fund of Mandatory Reserves (FMR) and M_s monetary aggregate over the period from February to July 2018 were received on the basis of models of time-series of respective indices calculated by the CBR1 over the period from October 1998 to December (November for M_{\circ} time series) 2017. Table 8 presents the results of calculations of forecast values and actual values of those indices in the same period of previous year. It is to be noted that due to the fact that the monetary base is an instrument of the CBR policy, forecasts of the monetary base on the basis of time-series models are to a certain extent notional as the future value of that index is determined to a great extent by decisions of the CBR, rather than the inherent specifics of the series.

In February–July 2018, the monetary base will be contracting at an average monthly rate of 0.2%, and the monetary index M2 at an average rate of 0.1%.

INTERNATIONAL RESERVES

This section presents the outputs of the statistical estimation of such future values of the international reserves of the Russian Federation² as were received

Jun 17		-0.3		1.4
Jul 17		1.8		1.0

Note: over the period from October 1998 to December (November) of 2017, all the time series of monetary indices were attributed to the class of series which are stationary in the first-order differences and have an explicit seasonal component.

The data on the specific month is given in accordance with the methods of the CBR as of the beginning of the following

² The data on the volume of the gold and foreign exchange reserves is presented as of the first day of the following month.

on the basis of evaluation of the model of time series of the gold and foreign exchange reserves on the basis of the data released by the CBR over the period from October 1998 to December 2017. That index is forecast without taking into account a decrease in the amount of reserves due to foreign debt payment and for that reason the values of the volumes of the international reserves in the months where foreign debt payments are made may happen to be overestimated (or otherwise underestimated) as compared to the actual ones.

Subsequent to the forecast results for February–July 2018, the international reserves will be growing at an average monthly rate of 0.5%.

FOREIGN EXCHANGE RATES

The model calculations of prospective values of the foreign exchange rates (RUB per USD and USD per euro) were made on the basis of assessment of the time series models (ARIMA) and structural models (SM) of the relevant indicators released by the Central Bank of Russia as of the last date of each month over the periods from October 1998 to January 2018 and from January 1999 to January 2018¹, respectively.

In February–July 2018, USD/RUB average exchange rate is forecast along two models in the amount of RUB 56.17 for USD along two models. Over the period under review, Euro/USD exchange rate is forecast at USD 1.23 per 1 euro.

THE LIVING STANDARD INDEXES

This section (Table 12) presents calculations of forecast values of indices of real wages, real disposable income and real income ² as were received on the basis of the model of time series of respective

Note: over the respective periods, the series under review were identified as integrated series of the first order with a seasonal component.

indices computed by Rosstat and taken over the period from January 1999 to January 2018. The above indices depend to a certain extent on the centralized decisions on raising of wages and salaries to public sector workers, as well as those on raising of pensions, scholarships and allowan-

¹ The authors use the IMF data over the period from January 1999 to November 2017. The data over the December 2017 and January 2018 was obtained from the foreign exchange rate statistics website: www.oanda.com

² Real cash income is a relative index which is calculated by means of division of the index of the nominal size (which was actually formed in the period under review) of households' cash income by the CPI. Real disposable cash income is cash income minus mandatory payments and contributions. (See: Rossiisky Statistichesky Ezhegodnik, Moscow, Rosstat, 2004, p. 212).

ces; such a situation introduces some changes in the dynamics of the indices under review. As a result, the future values of the indices of real wages and real disposable income calculated on the basis of the series which last observations are either considerably higher or lower than the previous ones due to such a raising may differ greatly from those which are implemented in reality.

According to the results presented in *Table 11*, average monthly growth of real disposable cash income is forecast at the rate of 1.9% compared to the previous year; real cash income – 0.7%. Real accrued wages are projected to grow on average by 3.7%, according to forecast.

EMPLOYMENT AND UNEMPLOYMENT

For the purpose of calculation of the future values of the employment (of the number the gainfully employed population) and the unemployment (the

total number of the unemployed), models of the time series evaluated over the period from October 1998 to November 2017 on the basis of the monthly data released by Rosstat¹ were used. The unemployment was calculated on the basis of the models with results of the findings from business surveys² too.

It is to be noted that feasible logical inconsistencies³ in forecasts of employment and unemployment which totals should be equal to the index of economically active population may arise due to the fact that each series is forecast individually and not as a difference between the forecast values of the economically active population and another index.

Table 12 CALCULATION OF FORECAST VALUES OF THE INDICES THE EMPLOYMENT AND THE UNEMPLOYMENT

May 17	99.4	100.0	102.7
Jun 17	99.9	100.2	103.8
Jul 17	96.1	96.6	103.0

Note: for calculating purposes the series of the real disposable cash income, real cash income and real accrued wages in the base form were used (January 1999 was adopted as a base period). Over the period from January 1999 to January 2018, those series were attributed to the class of processes, which are stationary in differences and have an explicit seasonal component.

² The model is evaluated over the period from January 1999 to November 2017.

³ For example, deemed as such a difference may be a simultaneous decrease both in the employment and the unemployment. However, it is to be noted that in principle such a situation is possible provided that there is a simultaneous decrease in the number of the economically active population.

Table 12, cont'd

	Employment (ARIMA)		U	nemployment (A	RIMA)	Unemployment (BS)				
	Million people	Growth on the respective month of previous year (%)	Million people	Growth on the respective month of previous year (%)	% of the index of the number of the gainfully employed population	the respective month of previous		% of the index of the number of the gainfully employed population		
For reference: actual values in the same periods of 2017 (million people)										
Feb 17	7 71.3 4.2									
Mar 17		71.8	4.1							
Apr 17		71.7	4							
May 17		71.9	3.9							
Jun 17		72.1	3.8							
Jul 17		72.4	3.9							

Note: over the period from October 1998 to November 2016, the series of employment is a stochastic process which is stationary around the trend. The series of unemployment is a stochastic process with the first order integration. Both indices include seasonal component.

According to ARIMA-model forecast (*Table 12*), in February–July 2018, the increase of the number of employed in the economy will average 0.8% per month against the corresponding period of the previous year

The decrease of the total number of jobless is forecast to average 2.5% per month against the same period of last year.
