INTRODUCTION TO ALL THE ISSUES

This paper presents calculations of various economic indicators for the Russian Federation in *June–November* of 2017, which were performed using time series models developed as a result of research conducted by the Gaidar Institute over the past few years¹. A method of forecasting falls within the group of *formal* or *statistical* methods. In other words, the calculated values neither express the *opinion* nor *expert evaluation* of the researcher, rather they are calculations of future values for a specific economic indicator, which were performed using formal ARIMA models (p, d, q) given a prevailing trend and its, in some cases, significant changes. The presented forecasts are of inertial nature, because respective models rely upon the dynamics of the data registered prior to the moment of forecasting and depend too heavily on the trends, which are typical of the time series in the period immediately preceding the time horizon to be forecast. The foregoing calculations of future values of economic indicators for the Russian Federation can be used in making decisions on economic policy, provided that the general trends, which were seen prior to forecasting for each specific indicator, remain the same, i.e. prevailing long-term trends will see no serious shocks or changes in the future.

Despite that there is a great deal of data available on the period preceding the crisis of 1998, models of forecasting were analyzed and constructed using only the time horizon which followed August 1998. This can be explained by the findings of previous studies², which concluded, among other key inferences, that the quality of forecasts was deteriorated in most of the cases when the data on the pre-crisis period was used. Additionally, it currently seems incorrect to use even shorter series (following the crisis of 2008), because statistical characteristics of models based on such a short time horizon are very poor.

Models for the economic indicators in question were evaluated using standard methods of time series analysis. Initially, the correlograms of the studied series and their first differences were analyzed in order to determine the maximum number of delayed values to be included into the specifications of a model. Then, the results of analyzed correlograms served as the basis for testing all the series for weak stationarity (or stationarity around the trend) using the Dickey–Fuller test. In some cases, the series were tested for stationarity around the segmented trend using Perron and Zivot–Andrews tests for endogenous structural changes³.

The series were broken down into weak stationary, stationary near the trend, stationary near the trend with structural change or difference stationary, and then models, which corresponded to each type (regarding the levels and including, if necessary, the trend or segmented trend or differences), were evaluated. The Akaike and Schwartz information criteria, the properties of models' residuals (lack of autocorrelation, homoscedasticity and normality) and the quality of the in-sample-forecasts based on these models were used to choose the best model. Forecast values were calculated for the best of the models constructed for each economic indicator.

Additionally, the Bulletin presents future monthly values of the CPI, which were calculated using models developed at the Gaidar Institute, and volumes of imports/exports from/to all countries, which were calculated using structural models (SM). The forecast values based on the structural models may, in some cases, produce better results than ARIMA-models do, because structural

Further Evidence on the Great Crash, the Oil-Price Shock, and Unit-Root Hypothesis. *Journal of Business and Economic Statistics*, 1992, 10, pp. 251–270.

models are constructed by adding information of the dynamics of exogenous variables. Besides, the use of structural forecasts in making aggregated forecasts (i.e. forecasts obtained as average value from several models) may help make forecast values more accurate.

The dynamics of the Consumer Price Index was modeled using theoretical assumptions arising from the monetary theory. The following was used as explanatory variables: money supply, output volume, the dynamics of the ruble-dollar exchange rate, which reflects the dynamics of alternative cost of money-keeping. The model for the Consumer Price Index also included the price index in the electric power industry, because the dynamics of manufacturers' costs relies heavily on this indicator.

The baseline indicator to be noted is the real exchange rate, which can influence the value of exports and imports, and its fluctuations can result in changes to the relative value of domestically-produced and imported goods, though the influence of this indicator turns out to be insignificant in econometric models. Global prices of exported resources, particularly crude oil prices, are most significant factors, which determine the dynamics of exports: a higher price leads to greater exports of goods. The level of personal income in the economy (labor costs) was used to describe the relative competitive power of Russian goods. Fictitious variables D12 and D01 – equal to one in December and January and zero in other periods – were added so that seasonal fluctuations were factored in. The dynamics of imports is effected by personal and corporate incomes whose increase triggers higher demand for all goods including imported ones. The real disposable cash income reflects the personal income; the Industrial Production Index reflects the corporate income.

The forecast values of foreign exchange rates were also calculated using structural models of their dependence on global crude oil prices.

The forecast values of explanatory variables, which are required for forecasting on the basis of structural models, were calculated using ARIMA models (p, d, q).

The paper also presents calculations of the values of the Industrial Production Index, the Producer Price Index and the Total Unemployment Index, which were calculated using the results of business surveys conducted by the Gaidar Institute. Empirical studies show¹ that the use of series of business surveys as explanatory variables ² in forecasting models can make forecasting more accurate on the average. Future values of these indicators were calculated using ADL-models (seasonal autoregressive delays were added).

The Consumer Price Index and the Producer Price Index are also forecast using large datasets (factor models – FM). The construction of factor models relies basically on the evaluation of the principal components of a large dataset of socio-economic indicators (112 indicators in this case). The lags of these principal components and the lags of the explanatory variable are used as explanatory variables in these models. A quality analysis of the forecasts obtained for different configurations of the factor models was used to chose a model for the CPI, which included 9th, 12th and 13th lags of the four principal components, as well as 1st and 12th lags of the variable itself, and a model for the PPI, which included 8th, 9th and 12th lags of the four principal components, as well as 1st, 3rd and 12th lags of the variable itself.

All calculations were performed using the Eviews econometric package.

¹ See, for example: V. Nosko, A. Buzaev, P. Kadochnikov, S. Ponomarenko. *The Analysis of Forecasting Parameters of Structural Models and Models with Business Surveys' Findings*. Moscow, IEP, 2003.

² Used as explanatory variables were the following series of the business surveys: the current/expected change in production, the expected changes in the solvent demand, the current/expected price changes and the expected change in employment.

trend with two endogenous structural changes. The time series of other chain indices are stationary at levels.

¹ It is to be noted that for making of forecasts so-called "raw" indices (without seasonal and calendar adjustment) were used and for that reason in most models existence of the season factor is taken into account and, as a consequence, the obtained outputs reflect the seasonal dynamics of the series.

²⁰¹⁷ MODEL CALCULATIONS OF SHORT-TERM FORECASTS.

INDUSTRIAL PRODUCTION AND RETAIL SALES

Industrial production

For making forecast for June–November of 2017, the series of monthly data of the indices of industrial production released by the Federal State Statistics Service (Rosstat) from January 2002 to March 2017, as well as the series of the base indices of industrial production released by the National Research University Higher School of Economics (NRU HSE¹) over the period from January 2010 to April 2017 were used (the corrected value of January 2010 was equal to 100%). The forecast values of the series were calculated on the basis of ARIMA-class models. The forecast values of the Rosstat and the NRU HSE indices of industrial production are calculated using business surveys (BS) as well. The obtained results are shown in Table 1.

As seen from *Table 1*, the index of industrial production computed by Rosstat posted average² growth of 1.7% in June–November 2017 compared to the same period of the previous year on industry as a whole. For the index of industrial production computed by the NRU HSE, this indicator constitutes 1.9%.

The average monthly values of the index of industrial production for mining computed by Rosstat and the NRU HSE for June–November 2017 come to 1.4% and 1.3%, respectively.

In June–November 2017 in comparison with the same period of last year, the average growth of the Rosstat index of industrial production for manufacturing comes to (-0.8%) and the NRU HSE index to (-4.6%). The average monthly values of the Rosstat and the NRU HSE index for industrial production of food products constitute 4.2% and 4.4%, respectively. The production of coke and petroleum products is forecast to average (-3.6%) and (0.6%) for the Rosstat and NRU HSE indexes, respectively. The average monthly values of the index of industrial production for primary metals and fabricated metal products for June–November 2017 computed by Rosstat and the NRU HSE constitute (-4.7%) and 1.0%, respectively. Manufacturing of machinery and equipment is forecast to grow on average at 4.7% and 3.7% for the Rosstat

and the NRU HSE indexes, respectively.

The average growth of the index of industrial production of electricity, gas, and steam supply; air conditioning computed by Rosstat for June–November 2017 in comparison with the same period of the previous year constitutes (-0.2%); the same indicator for the NRU HSE index comes to (-3.2%).

Retail Sales

This section (Table 2) presents forecasts of monthly retail sales made on the basis of monthly Rosstat data over January 1999 – March 2017.

As seen from *Table 2*, the monthly trade turnover is forecast to grow on average at around 4.6% in June–November 2017 against the corresponding period of 2016. The monthly real trade turnover is forecast to stay at 1.1%.

two endogenous structural changes. The series of other chain price indices are stationary at levels.

FOREIGN TRADE INDICES

Model calculations of forecast values of the export and export to countries outside the CIS and the import and import from countries outside the CIS were made on the basis of the models of time series and structural models evaluated on the basis of the monthly data over the period from September 1998 to April 2017 on the basis of the data released by the Central Bank of Russia¹. The results of calculations are shown in Table 3.

Exports, imports, exports outside the CIS and imports from the countries outside the CIS are forecast to grow at 19.2%, 11.4%, 19.4%, and 15.3%, respectively in June–November 2017 against the same period of 2016. The average forecast surplus volume of the trade balance with all countries for June– November 2017 will amount to \$ 57.8bn which reflects growth by 38.6% on the same period of 2016.

DYNAMICS OF PRICES

The Consumer Price Index and Producer Price Index

This section presents calculations of forecast values of the consumer price index and producer price index (as regards both the industry in general and some types of its activities under the

National Industry Classification Standard (NICS)) made on the basis of the time-series models evaluated on the basis of the data released by Rosstat over the period from January 1999 to March 2017². Table 4 presents the results of model calculations of forecast values over June–November 2017 in accordance with ARIMA models, structural models (SM) and models computed with the help of business surveys (BS).

The consumer price index is forecast to grow at an average monthly rate of 0.4% in June–November 2017. The producer price index (PPI) for the same period is also forecast to average 0.5% per month. The producer price indexes are forecast to grow at average monthly rates in June–November 2017: for mining and quarrying 0.4%, manufacturing 0.7%, utilities (electricity, gas, and steam) 1.0%, food products 0.5%, textile and sewing industry 0.5%, wood products 0.3%, pulp and paper industry 0.3%, coke and refined petroleum 2.3%, for chemical industry 1.2%, for basic metals and fabricated metal 0.2%, for machinery and equipment 0.1%, and for manufacture of motor vehicles 0.6%.

The Cost of the Monthly per Capita Minimum Food Basket

This section presents calculations of forecast values of the cost of the monthly per capita minimum food basket over June–November 2017. The forecasts were made based on time series with use the Rosstat data over the period from January 2000 to March 2017. The results are shown in Table 5.

Talla

Note: the series of the cost of the monthly per capita minimum food basket over the period from January 2000 to March 2017 are stationary in the first-order differences.

¹ The data on the foreign trade turnover is calculated by the CBR in accordance with the methods for making of the balance of payment in prices of the exporter-country (FOB) in billion USD.

² Structural models were evaluated in the period from October 1998.

As can be seen from *Table 5*, the cost of the monthly per capita minimum food basket is forecast to grow compared to the corresponding period of the previous year. At the same time, the cost of the monthly per capita minimum food basket is forecast to average RUB 3,829.9. The cost of the

monthly per capita minimum food basket is forecast to average 3.1% compared to the level of the corresponding period of the previous year.

Indices of Freight Rates

This section presents calculations of forecast values of freight rate indices on cargo carriage¹, made on the basis of time-series models evaluated on the Rosstat data over the period from September 1998 to March 2017. Table 6 shows the results of model calculations of forecast values in June-November of 2017. It should be noted that some of the indices under review (for instance, the pipeline rate index) are adjustable ones and for that reason their behavior is hard to describe by means of the time-series models. As a result, the future values may differ greatly from the real ones in case of the centralized increase of rates in the period of forecasting or in case of absence of such an increase in the forecasting period, but with it taking place shortly before the beginning of that period.

According to the forecast results for June– November 2017, the composite freight rate index will increase on average 0.6% per month. In July 2017, seasonal growth of the index is expected by 3.8 p.p.

The index for motor load freight rate will decease at a monthly average rate of 0.1% in the course of given six months. The index for pipeline transport will be growing at a monthly average rate of 0.8%.

Table 6

Note: over the period from September 1998 to March 2017, the series of the freight rates index were identified as stationary ones; the other series were identified as stationary ones over the period from September 1998 to March 2017, too; fictitious variables for taking into account particularly dramatic fluctuations were used in respect of all the series.

This section presents calculations of such average monthly values of Brent crude prices (US\$ per barrel), the aluminum prices (US\$ per ton), the gold prices (\$ per ounce), the copper prices (US\$ per ton), and the nickel prices (US\$ per ton) over June–November 2017 as were received on the basis of nonlinear models of time series evaluated on the basis of the IMF data over the period from January 1980 to April 2017.

The crude oil price is forecast to average \$49.0 per barrel, which is above its corresponding yearearlier indexes on average by 4.4%. Aluminum prices are forecast to average \$1,960.0 per ton and their average forecast increment constitutes around 19.0% compared to the same level of last year. Gold prices are forecast to average \$1,340.0 per ounce. The copper prices are forecast to average

¹ The paper presents a review of the composite freight rate index on freight transport and the motor load freight rate index, as well as the pipeline rate index. The composite freight rate index is computed on the basis of the freight rate indices by individual types of transport: rail, pipeline, shipping, domestic water-borne, and motor load freight and air service (for more detailed information, pls. refer, for instance, to: *Prices in Russia*. The Official Publication of Goskomstat of RF, 1998).

\$5,601 per ton, and prices for nickel – around \$9,337 per ton. The average forecast price increase on gold constitutes around 3.0%, average increase of copper prices – around 16.0%, and average increase of nickel prices – 8.0% compared to the corresponding level of last year.

Note: over the period from January 1980 to April 2017, the series of prices of crude oil, nickel, gold, copper and aluminum are series of DS type.

MONETARY INDICES

The future values of the monetary base (in the narrow definition: cash funds and the Fund of Mandatory Reserves (FMR) and M_{2} monetary aggregate over the period from June to November 2017 were received on the basis of models of time-series of respective indices calculated by the CBR¹ over the period from October 1998 to May (April – for M, time series) 2017. Table 8 presents the results of calculations of forecast values and actual values of those indices in the same period of previous year. It is to be noted that due to the fact that the monetary base is an instrument of the CBR policy, forecasts of the monetary base on the basis of time-series models are to a certain extent notional as the future value of that index is determined to a great extent by decisions of the CBR, rather than the inherent specifics of the series.

THE FORECAST OF M₂ AND THE MONETARY BASE

	The N	Ionetary base		M_2
	Billion RUB	Growth on the previous month, %	Billion RUB	Growth on the previous month, %
Jun 17	8,830	-1.2	38,565	-0.6
Jul 17	8,932	1.2	38,790	0.6
Aug 17	8,837	-1.1	38,568	-0.6
Sep 17	8,928	1.0	38,788	0.6
Oct 17	8,833	-1.1	38,570	-0.6
Nov 17	8,924	1.0	38,786	0.6

For reference: actual value in the respective months of 2016 (growth on the previous month, %)

01	=oro (growen on ene pr	0,10,000 momony, , o)
Jun 16	-1,3	1.5
Jul 16	1,2	0.6
Aug 16	1.0	0.5
Sep 16	-0.4	0.4
Oct 16	0.5	-0.1
Nov 16	-1.1	-0.3

Note: over the period from October 1998 to May (April) 2017, all the time series of monetary indices were attributed to the class of series which are stationary in the first-order differences and have an explicit seasonal component.

During summer-autumn 2017, both monetary indexes will remain unchanged on average.

¹ The data on the specific month is given in accordance with the methods of the CBR as of the beginning of the following month.

INTERNATIONAL RESERVES

This section presents the outputs of the statistical estimation of such future values of the international reserves of the Russian Federation¹ as were received on the basis of evaluation of the model of time series of the gold and foreign exchange reserves on the basis of the data released by the CBR over the period from October 1998 to May 2017. That index is forecast without taking into account a decrease in the amount of reserves due to foreign debt payment and for that reason the values of the volumes of the international reserves in the months where foreign debt payments are made may happen to be overestimated (or otherwise underestimated) as compared to the actual ones.

Subsequent to the forecast results for June– November 2017, the international reserves will be growing by an average monthly rate of 0.4%.

FOREIGN EXCHANGE RATES

The model calculations of prospective values of the foreign exchange rates (RUB per USD and USD per euro) were made on the basis of assessment of the time series models (ARIMA) and structural models (SM) of the relevant indicators released by the Central Bank of Russia as of the last date of each month over the periods from October 1998 to May 2017 and from January 1999 to May 2017², respectively.

In June–November 2017, USD/RUB average exchange rate is forecast along two models in the amount of RUB 56.65 for USD.

Euro/USD exchange rate is forecast at USD 1.11 per 1 euro on average at the period under review.

Note: over the respective periods, the series under review were identified as integrated series of the first order with a seasonal component.

This section (Table 12) presents calculations of forecast values of indices of real wages, real disposable income and real income³ as were received on the basis of the model of time series of respective indices computed by Rosstat and taken over the period from January 1999 to April 2017. The above

¹ The data on the volume of the gold and foreign exchange reserves is presented as of the first day of the following month.

² The authors use the IMF data over the period from January 1999 to January 2017. The data over the period from February and March 2017 was obtained from the foreign exchange rate statistics website: www.oanda.com

³ *Real cash income* is a relative index which is calculated by means of division of the index of the nominal size (which was actually formed in the period under review) of households' cash income by the CPI. *Real disposable cash income* is cash income minus mandatory payments and contributions. (See: Rossiisky Statistichesky Ezhegodnik, Moscow, Rosstat, 2004, p. 212).

Table 11

indices depend to a certain extent on the centralized decisions on raising of wages and salaries to public sector workers, as well as those on raising of pensions, scholarships and allowances; such a situation introduces some changes in the dynamics of the indices under review. As a result, the future values of the indices of real wages and real disposable income calculated on the basis of the series which last observations are either considerably higher or lower than the previous ones due to such a raising may differ greatly from those which are implemented in reality.

According to the results presented in *Table 11*, average monthly decline of the real disposable cash income is forecast at the rate of 2.1% compared to the previous year, the real cash income -2.6%. The real accrued wages are projected to grow on average by 5.0%, according to forecast.

THE FORECAST OF THE LIVING STANDARD INDEXES

	Real disposable	Real cash	Real accrued						
	cash income	income	wages						
Forecast values according to ARIMA-models (% of									
the respective month of 2016)									
Jun 17	97.5	97.9	102.5						
Jul 17	97.0	96.8	105.6						
Aug 17	98.8	97.4	104.3						
Sep 17	96.2	96.1	105.1						
Oct 17	98.1	97.2	106.2						
Nov 17	99.7	98.9	106.2						
For refe	erence: actual values	in the resp	pective period						
C	of 2016 (% of the sam	ne period of	2015)						
Jun 16	95.5	95.1	101.1						
Jul 16	91.8	92.6	98.7						
Aug 16	90.0	92.4	102.7						
Sep 16	97.3	97.0	101.9						
Oct 16	94.0	94.9	100.4						
Nov 16	93.8	94.6	102.1						

Note: for calculating purposes the series of the real disposable cash income, real cash income and real accrued wages in the base form were used (January 1999 was adopted as a base period). Over the period from January 1999 to April 2017, those series were attributed to the class of processes, which are stationary in differences and have an explicit seasonal component.

EMPLOYMENT AND UNEMPLOYMENT

For the purpose of calculation of the future values of the employment (of the number the gainfully employed population) and the unemployment (the total number of the unemployed), models of the time series evaluated over the period from October 1998 to March 2017 on the basis of the monthly data released by Rosstat¹ were used. The unemployment was calculated on the basis of the models with results of the findings from business surveys² too.

It is to be noted that feasible logical inconsistencies³ in forecasts of employment and unemployment which totals should be equal to the index of economically active population may arise due to the fact that each series is forecast individually and not as a difference between the forecast values of the economically active population and another index.

According to ARIMA-model forecast (*Table 12*), in June–November 2017, the growth of the number of employed in the economy will average 0.8% per month against the corresponding period of the previous year.

The decrease of the total number of jobless is forecast to average 5.1% per month against the same period of last year.

¹ The index is computed in accordance with the methods of the International Labor Organization (ILO) and is given as of the month-end.

² The model is evaluated over the period from January 1999 to March 2017.

³ For example, deemed as such a difference may be a simultaneous decrease both in the employment and the unemployment. However, it is to be noted that in principle such a situation is possible provided that there is a simultaneous decrease in the number of the economically active population.

Table 12

CALCULATION OF FORECAST VALUES OF THE INDICES THE EMPLOYMENT AND THE UNEMPLOYMENT

Employment (ARIMA)		Unemployment (ARIMA)				Unemployment (BS)
